Antibacterial and Antifungal Activities of Isolated AlliCin (Part Second)

F. Rehman* and Samya Mairaj

Department of Analytical Chemistry Faiz-E-Aam Degree College, Meerut.

Abstract

The pharmaceutical importance of Allium Sativum is due to the presence of carbohydrate, protein, vitamins, essential metal and organosulpher compounds. Allicin is one of the active ingredients of freshly crushed garlic homogenates and showed a wide spectrum activity. The antimicrobial activity of different concentration of allicin against gram positive and gram negative bacterial isolate was studied by standard protocols. The maximum zone of inhibition has been observed in S. typhi and minimum for E. Coli. Alternaria alternata has been shown maximum percentage of inhibition while minimum for Aspergillus niger. The minimum inhibitory concentration (MIC) varies bacteria to bacteria and fungus to fungus respectively. The effect of time, temperature and pH were also studied. The antibacterial efficacy was maintained at room temperature for maximum one week and maintains for longer time only at low temperature. Antimicrobial activity of garlic come from allicin, is mainly due to S-S and S-O bond which has the ability to react with thiol containing enzyme to form S-thiolation product, the broad spectrum antimicrobial effects of allicin is due to the multiple inhibitory effects on various thiol dependent enzymatic systems. The results indicate that allicin has antimicrobial activity.

Keywords: allicin, antimicrobial activity, Richard's liquid medium

INTRODUCTION

Despite of all progress in synthetic chemistry and biotechnology, plants are still on indispensible source of medicinal preparation in both preventive and curative. Hundreds of species are recognized as having medicinal value and many of those are considered to play a beneficial role in health care. In recent years renewed interest has been shown in the used of medicinal plants and scientific studies are beginning to explain some of the curative phenomena associated with traditional herbal remedies. The therapeutic action of the plant depends on its chemical constituents. The botanical relationship of a particular plant to well known drug plants may be an indication of a potential therapeutic interest. Indeed, chemical relationship based on secondary metabolites specially found in certain genera and families has been observed and is made use of in botanical taxonomy. In industrialized countries health providers have reduced their dependence on the plant kingdom. The majority of developing countries still rely on herbal remedies. Indeed, phyto medicines are beginning to link traditional/homeopathic medicine and modern (allopathic) medicine. WHO estimates that approximately 80 percentage of the developing world’s population meet their primary health care needs through traditional medicine. In India, garlic has been used to prevent wound infection and food spoilage[1], and as antiseptic, antiplatelet[2], anticancer[3-7],antithrombotic[8-9], antifungal[10-11], antibacterial [12-14], antiviral[15],antihypertensive[16],antithrombotic [17], antioxidant[18-20]. Garlic exhibit a broad antibiotic activity against both gram positive and gram negative bacteria that have become resistant to antibiotics[21] and effective against many common pathogenic bacteria[22].The antimicrobial activity of garlic is only due to thiosulfinates compound, so, garlic extract used in the treatment of asthma, arthritis, sciatica, lumbago backache, bronchitis, chronic fever, tuberculosis, rhinitis, malaria, obstinate, skin disease including leprosy, leucoderma, discolouration, itches, indigestion, colin pain, enlargement of spleen, pales, fistula, fracture of bone, anemia, jaundice, epilepsy, contract and night blindness, tumor, ulcer, managing high cholesterol level, hysteria, dropsy, scurvy,vampires and act as powerful antioxidant. It detoxifies the body cleansing the kidney and increase the urine flow. During the past two decade more attention has been given to uncovering the benefits of garlic sulfur compound in relation to cancer. Some garlic constituents have been shown to alter activation of carcinogen and cause growth inhibition of tumor cells. Allicin and wide range of other organosulfurate compounds which are known to be the constituents linked to the garlic properties. Allicin (2-propene-1-sulfinothionic acid 5-2-propenyl ester is a thioester of sulfonic acid and exhibit antimicrobial[23-26], antiviral[27], antioxidant[23], anticancer[28], and has significant anticholesterol activity[29], so, used to prevent heart diseases including artherosclerosis (hardening of arteries), high blood pressure, sugar, digestive disorder, reduce platelet aggregation, hyperlipidermia [30], reduce the incidence of a multitude of chemically induced tumor and help for AIDS patient to treat cryptosporidium and toxoplasmosis, and used as antihypertensive[30]. Allicin has a wide spectrum of antibacterial activity against numerous gram(+) and gram(-) bacteria such as E.coli, Salmonellaenterica, Shigella, Enterococcus faecalis, Staphylococcus aureous, Streptococcus, Klebsiella aerogenes, Pseudomonas aeruginosa, Proteus vulgaris, Candida albicans and Streproproteus [31-37]. Pharmacokinetic studies indicate that allicin will reach a maximum level in the blood after 30-60 minutes and may still be present 72 hours later with more than 85% clearance through urine and faecal path-way[38]. Similarly allicin have significant enhancing effects on the immune system. It has been reported that the antibiotic activity of 1 mg of allicin is equated to that of 15 IU of pencillin[39] In the present communication we deals to highlight the antifungal and antibacterial activity of the allicin at different concentration, temperature and pH against different bacteria and fungi by using standard protocol.
EXPERIMENT

Chemical composition of allium sativum

The chemistry of garlic do not fully understand because each tiny clove contains the potential for almost 200 chemicals, that can be generated and interact with each other in a number of ways but the major components are as sulfur compound (alliin, allicin and ajoene), volatile oil, enzyme (alliinase, peroxidase and miracynase, bioflavonoids (quercetin, cyaniding, allistain-I and II) carbohydrates (glucose and sucrose), protein, saponine, allinase enzyme, vitamin A, B, B₃, B₅, B₆, C, E, minerals such as Se, Ca, Fe, Mg, Mn, K, Na, Zn, amino acids (cystein, glutamine iso leucine and methionine), flavonoids, scardinine and antioxidant.

Isolation of Allicin

Allicin (2-propene-1-sulfinothinic acid S-2-propenyl ester or diallyl thisulfinate) is a bright yellow oily liquid with a characteristic garlic odour [40]. It is very unstable and can bestabilized with preserved pharmacological activity by producing inclusion complexes with β-cyclodextrins[41]. Naturally allicin (diallyl thiosulfinate) does not occur in allium sativum, instead it is found in the form of the amino acid- alliin (S-allyl cystein sulphoxide). When it crushed, the alliin react with phosphopyridoxal enzyme allinase located in separate parts of garlic clove [42]. In this transformation an unstable alliin- alliinase complex is formed, which further subjected to dehydration by pyridoxal phosphate and transformed to allyl sulfinic acid, pyruvic acid and ammonia [43]. Allyl sulfinic acid transformed to allicin by self condensation. Complete transformation occurs in 10 -15 minutes at optimum temperature (33°C) and pH (6.5). Allinase enzyme becomes inactive in acidic medium, so this transformation can be inhibited up to 90% in the presence of retinol and hydroxyl amine sulfate solution by blocking the flavin components of this enzyme. Allinase is irreversibly deactivated below a pH of 3, so allicin is generally not produced in the body by the consumption of allium sativum.

Synthesis of allicin:

Allicin was synthesized by standard protocols [44-47].

ANTIMICROBIAL STUDIES

a. Antibacterial screening

The antibacterial activity of the test compound were measured by paper disc diffusion method, using agar nutrient medium and 5 mm diameter paper discs of whatman No.1 filter paper discs, were soaked in a solution of known amount (0.4 to 0.9% w/v) of test compound dried and laid on the surface of petri-plates which were already seeded with the test organism. All the agar dishes were then incubated in an incubator at 27 ± 1°C for about 48 hours. After the incubation period, the growth of the microorganism was studied as inhibition zone (mm), around each disc in the form of turbid layer, except in the region where the concentration of antibacterial agent is above the MIC and zone of inhibition is seen. The size of the zone of inhibition depends upon the sensitivity of the organism, nature of the culture medium, incubation condition, rate of diffusion of the agent and the concentration of the antibacterial agent on the filter paper.

b. Antifungal screening

The antifungal activity of different concentrations (0.40 to 0.90% w/v) of test compound was measured by determining the growth of test fungi by dry weight increase method and Richard liquid medium used as culture medium [48]. The test compounds of varying concentration were directly added in a Richard liquid medium having interested fungus in a sterilized chamber and was kept for seven days in an incubation chamber at 27 ± 1°C. Media with test solution served as treated while without them as check. The resultant mycelial mats in each set were carefully removed, washed, dried and then weighed separately. The percentage of inhibition was calculated by the following formula

\[
\text{Percentage inhibition of fungal growth} = \frac{(C_g - T_g) \times 100}{C_g}
\]

where, \(C_g\) = Average growth in the check set
\(T_g\) = Average growth in the treated set
c. Effect of pH and temperature on antibacterial and antifungal activity of allicin

The effect of pH on the antibacterial and antifungal activity of allicin at room temperature was tested by adjusting pH with 1N NaOH and / or 1N HCl and allowed to stand for 4 hrs at room temperature. The activity of allicin was tested by paper disc agar diffusion method and by dry weight increase method. The thermal stability of allicin has also been determined at different temperatures.

RESULTS AND DISCUSSION

Antimicrobial activities

Allicin is considered to be the most potent antibacterial agent in crushed garlic extract and used to treat methicillin resistant staphylococcus aureus(MRSA) that have become resistant to all penicillin drugs, like methicillin, oxacillin and amoxicillin. Allicin manifests a wide spectrum of antibacterial activity against numerous gram(+)ve and gram(-)ve bacteria and fungus such as Escherichiacoli, Salmonelenterica, Shigella, Enterococcus faecalis, Staphylococcus aureus, Streptococcus, Klebsiella erogenes, Pseudomonas aeruginosa, Proteus vulgaris, Streproproteus, Candida albicans [49-56], aspergillus flavus, aspergillus niger and cryptococcus neoformons[26]. Cyclodextrin complex of allicin exhibit more antimicrobial activity than allicin against Staphylococcus aureus, Escherichia coli, Pseudomonas aeruginosa bacteria and Candida albicans and Aspergillus niger. Allicin is recommended as co-therapy for the infections causes by Mycobacterium tuberculosis, an acid-resistant bacterium [57].The antifungal and antibacterial data of the graded concentrations of allicin against different bacteria and fungus were recorded in the table[1-3]fig.[1-3].The observed results reveal that the antibacterial and antifungal activity of the compound is directly proportional to the concentration of the test compound and differ from bacteria to bacteria and fungus to fungus. The maximum zone of inhibition has been observed in Bacillus subtitis and minimum for A. hydrophilia. On the other hand minimum percentage of inhibition was exhibited against Alternaria alternata & minimum against Aspergillus flavus. The antibacterial outcome of allicin is of a broad spectrum, and maximum zone of inhibition has been observed in S. typhi and minimum zone for E. coli.

It has been noted that the affinity of allicin was effected by the pH of the medium and temperature. The maximum zone of inhibition has been noted at the original pH against all tested microbes, while moderate activity has been observed at the neutral pH, results reveals that antimicrobial activity of allicin decreases with the increase of the pH value, which are accordance with Tynecka et al[59].

Antimicrobial activity of allicin also effected by temperature, its values decreases with the increase of temperature, and completely destroyed at 80°C to 90°C, which was supported by several researcher[60].

Figure 2
Antibacterial Activity of Allicin against different bacteria at different conc.
Mechanism—Antimicrobial agents interfere chemically with the synthesis of function of vital components of microorganism in the different ways. Inhibitors of cell wall synthesis, inhibitors of cell membrane, inhibitors of biosynthesis (i.e. production of purines, pyrimidine, A.A., Vitamins, protein, DNA, RNA), inhibitors of energy production (inhibit the respiration or by uncoupling of oxidative phosphorylation). The biological activity of allicin is to be related to a combination of the following factors.
1. Its activity as an antioxidant.
2. Its ability to attack the sulphur [SH] group of enzymes and proteins and modify their activities.
3. Its ability to rapidly penetrate into cells through the cell membrane.

Antimicrobial activity of allicin is mainly due to S-S and S-O bond which has the ability to react with thiol containing enzyme[L-cysteine] to form the S-thiolation product S-allyl mercaptocysteine which is characterized by NMR and Mass spectroscopy. It has been noted that in amoeba parasite, allicin was found to strongly inhibit the cysteine proteinases, alcohol hydrogenases [53] Inhibition of these enzymes was noted at rather low concentrations (< 10 µg/ml). Allicin also irreversibly subdued the well known thio-protease papain. Allicin also inhibits other bacterial enzymes such as the acetyl-co-A forming systein consisting of acetate kinase and phosphotransacetyl-co-A synthetase[54]. Allicin was found to partially inhibit the DNA and protein synthesis, but the effect on RNA was immediate, suggesting that this could be a primary target of allicin action [55].

**CONCLUSION**

It may be concluded from the study that allicin appears to satisfy all of the criteria for antimicrobial agents. Since the introduction of antibiotics, there has been
tremendous increase in the resistance of many bacterial pathogens. Scientists advance in their search for new bacterial targets to attack, bacteria evolve and as a result a large number of bacterial species have become resistant to antibacterial drugs. Hence, search for new antimicrobials is very essential in recent times. In view of the strong antimicrobial activity of allicin, research should continue to modify the isolated allicin by chemical process to form more potent against different studies and more dose-response preclinical studies and clinical studies should be done to develop noble drug or drug precursor.
