**ABSTRACT**

Plant diseases are characterized by wilting, moldy coatings, rusts, blotches, scabs and rotted tissue. They are often encouraged by wet weather, poor drainage or inadequate airflow. Some fungal problems can be controlled by reducing high moisture conditions and by cutting away diseased plant parts. In most cases however, a fungicide will be required. The organic fungicides we offer are least-toxic and earth-friendly. For best results apply early, before diseases become aggravated. An excellent organic fungicide, Sulfur Plant Fungicide is a finely ground wettable powder containing 90% elemental sulfur, Control diseases of fruits, vegetables and flowers and effective against powdery mildew, rust, scab, brown rot, rose black spot and many more. There is large number of chemical compounds for the protection of crops available commercially in the market but their effects depends on the climate, type of soil, and other physical parameters. The interactions of proposed fungicides with the macromolecule of the parasite are dependent on the stereochemistry of these compounds. In order to design more effective synthetic fungicides, it is necessary to analysis the three dimensional structure of these compounds and if possible the receptor molecule .Recently it has been observed that some of the fungicides are loosing their effects. if their structures are known, So analogous compounds can be designed as substitute.

## KEYWORDS

X-ray crystallography, Systemic fungicides, Triazole structure

## INTRODUCTION

Lime-sulfur, a fungicide composed of inorganic sulfur and lime, is commonly used today to control a variety of diseases such as plum pockets, black knot, black spot of rose, and a number of raspberry diseases. Lime-sulfur was originally developed in 1851 by Grison who was the head gardener at the vegetable houses in Versailles, France. Grison boiled "flowers of Sulphur", freshly slaked lime, and water for 10 minutes, drew off the clear liquid and mixed it with water. He then used this solution to protect plants against mildews. The solution was originally known as the "Grison Liquid" or "Eau Grison". In 1886, lime-sulfur was used to control peach leaf curl in California.

Sulfur is the only ingredient in the mix that is toxic to pathogens. It is able to kill pathogens through direct contact or fumigation (sulfur vapors). The vapor action of sulfur allows the fungicide to be effective from a distance and is important in killing spores of powdery mildew. Once taken up by the fungus, sulfur disrupts the transfer of electrons causing the reduction of sulfur to hydrogen sulfide (H<sub>2</sub>S), which is toxic to most cellular proteins.

Sulfur itself is also toxic to certain plant species and is capable of causing a phytotoxic reaction. As a result, lime has been added to the mix to reduce the phytotoxicity of sulfur. The more lime added to the mix the less phytotoxic. In general, lime is considered a "softeners" for the plant.

According to the label, lime-sulfur can be applied as a dormant season fungicide or as a growing

season spray. Dormant season applications need to be applied in late winter or early spring when temperatures are above freezing, but before leaves are present on the plant. Growing season applications can be made after leaves are present on the plant, but should be applied in the early morning or late afternoon to avoid burning. Plant damage caused by lime-sulfur is most severe during dry weather when temperatures reach 80 degrees to 95 degrees F. Lime-sulfur is corrosive to the eyes and harmful if swallowed, inhaled, or absorbed through the skin. Appropriate precautions according to the label should be taken when applying lime-sulfur. Thoroughly read the label before purchasing, handling, or applying lime-sulfur.

is a contact fungicide and their Symbol is S but their Chemical formula are S<sub>8</sub>. Atomic mass of Sulphur is equal to 32.063 \*8 = 256.53. The Sulphur structure is rhombic or monoclinic nature.

### **Experimental procedure**

Yellow well formed crystals of size 0.30 x 0.20 x 0.20 mm are obtained by slow evaporation from a solution of Toluene and Acetone at 297°K temp within 5-7 days. These contact fungicide is soluble in water, Acetone, Toluene, and Methanol but mostly soluble in Toluene (C<sub>6</sub>H<sub>5</sub>CH<sub>3</sub>) at temperature 20-25 degree..Table 1 shows some important properties of Sulphur

**Table 1**  
**Sulphur (Contact fungicide).**

**Solubility:** In water is greater than 20-25 degree C. The solubility of other Chemical solvent are :- 1. Acetone (CH<sub>3</sub>COCH<sub>3</sub>) 2. Toluene (C<sub>6</sub>H<sub>5</sub>CH<sub>3</sub>) 3. H<sub>2</sub>O and 4. Methanol (CH<sub>3</sub>OH) etc.

**Information about Sulphur (Contact fungicide)**

| <b>Fungicide Name</b> | <b>Use Solvent</b>         | <b>Mfd Date</b> | <b>Grow time period</b> | <b>Size/shape</b> | <b>color</b> | <b>Type</b>    |
|-----------------------|----------------------------|-----------------|-------------------------|-------------------|--------------|----------------|
| Sulphur (Contact)     | Tol.+Ace+ H <sub>2</sub> O | 08/02/11        | 5-7 Days                | Rectangular       | yellow       | Single crystal |

The ORTEP diagram and Packing diagram of Sulphur are solved using by SHELXS-97. The unit cell parameters a, b, and c and angle  $\alpha$ ,  $\beta$  and  $\gamma$  are determined by automatic computerized four circle Enraf- Nonius CAD-4 diffractometer.

**Data collection and structure solution**

The Sulphur fungicide single crystal data collection are on a computerized automatic CAD- 4 Enraf Nonius 4- circle diffractometer or Enraf Nonius CAD-4 F and CAD 4-MV31 diffractometer. The data collection is done on  $\omega$ -2 $\theta$  scan mode by four circle diffractometer. Each intensity measurement involved in a scan

over the reflection peak , a back ground measurement at each end of the scan range and measurement of peak height. The structure determination is carried out on VAX machine using SHELXS – 97.All the non hydrogen atoms are located in the beginning itself.

### **Refinement**

The x, y and z are positional coordinates, which were measured from and isotropic temperature factors were subjected to refinement by SHEIXL -97 refinement computer program. After so many cycles of refinement the R dropped to 0.0316as shown in table 2.
